Architecture Overview

The Apollo Analysis Engine is a data-validated instantiation of the Scout Entry Engine scoring framework, specifically calibrated and verified against actual multi-timeframe data for APOLLO Hospitals (NSE: APOLLOMICR). While the generic Scout Engine Scoring Matrix defines the abstract specification with 22 signals across four pools, the Apollo Analysis Engine represents the concrete signal configuration that was tested and validated on real 4H, Daily, and Weekly price data during the March-April 2026 recovery period. This document serves as the definitive reference for the exact scoring distribution, signal conditions, point allocations, and verified data points that comprise the Apollo-specific engine implementation.

The engine was designed to solve a critical timing problem: the generic Scout Engine specification includes several signals that rely on continuous formulas (RSI Reversal with power-curve scaling, Recovery Momentum with rate-based thresholds, and Price Approaching TP with proximity scaling). For a first-pass backtest and analysis, these formulaic signals were replaced with discrete, threshold-based equivalents that are easier to implement, verify against historical data, and reason about during signal-by-signal analysis. The result is an engine with fewer total signals (19 vs 22 in the generic matrix) but with each signal having a clearly defined ON/OFF condition that can be checked against any bar of historical data.

Two-Engine Architecture

The Apollo Analysis Engine operates within the same two-engine framework as the generic Scout Engine. The Scout engine handles early detection of recovery signals that fire before price confirms a breakout, while the companion Sentinel Engine handles confirmed-trend entries with heavier price-structure and confirmation weighting. The Apollo Analysis Engine is the Scout component, optimized for catching recoveries 5-15% below the breakout level. For APOLLO, this meant detecting the recovery at Rs 208 on April 8, 2026, approximately one full day before the explosive breakout to Rs 232 on April 9.

Dimension	Scout Engine (This Document)	Sentinel Engine (Future)
Purpose	Catch recoveries before breakout confirmation	Enter after trend re-establishment is verified
Target Price	5-15% below breakout level	At or above breakout level
Pool A (RSI)	Heavy (42 pts) - trough + recovery momentum + 4H crossover	Standard (30 pts) - RSI must already be above 50
Pool B (Structure)	Moderate (25 pts) - 4H-level signals, approaching levels	Heavy (35 pts) - Price > MA, higher highs/lows confirmed
Pool C (Confirm)	Moderate (18 pts) - cross-TF alignment	Heavy (30 pts) - cross-TF alignment required
Threshold	Score >= 75 for Standard Entry	Score >= 80 for Full Entry
Position Size	0.5-1x standard (smaller, wider SL)	1-1.5x standard (full, tighter SL)
APOLLO Example	Apr 8 at 208.05 (score ~98)	Apr 9 at 232.52 (all conditions met)

Key Differences from Generic Scout Engine

The Apollo Analysis Engine differs from the generic Scout Engine Scoring Matrix in several important ways. These differences are not errors but deliberate simplifications made to enable data-validated signal verification. The

generic matrix uses continuous formula-based scoring (power-curve RSI reversal, rate-based recovery momentum, proximity-scaled approaching TP), while the Apollo engine uses discrete binary signals with fixed point values. This trade-off sacrifices some scoring granularity for complete verifiability: every signal in the Apollo engine can be definitively confirmed as firing or not firing on any given bar by examining the raw CSV data. The table below summarizes the key structural differences between the two.

Aspect	Generic Scout Engine	Apollo Analysis Engine
Pool A Max	45 pts (10 signals, continuous formulas)	42 pts (6 signals, discrete thresholds)
Pool B Max	25 pts (5 signals, proximity scaling)	25 pts (5 signals, binary conditions)
Pool C Max	15 pts (3 signals, divergence-based)	18 pts (4 signals, threshold-based)
Bonus A Max	12 pts (3 signals)	8 pts (3 signals, simplified)
Bonus B Max	13 pts (5 signals, uptrend-gated)	10 pts (3 signals, simplified)
Core Cap	85 pts	85 pts (min of 100, pool sum)
Max Score	110	103
RSI Scoring	Continuous (power-curve, rate-based)	Discrete (gained >= N points from trough)
Price TP Signal	Proximity scaling (0-11.5 pts)	Binary: Close > TP28 on 4H (7 pts) + Approaching on D (5 pts)
4H Signals	In Pool A (divergence per-TF) and Pool B (TP flatten, WC flatten)	In Pool A (trough, momentum, crossover) and Pool B (Close > TP28, Close > WC50)
Verification	Specification only, no data validation	All signals verified against actual APOLLO data

Timeframes

The Apollo Analysis Engine operates on three timeframes: 4-Hour (4H), Daily (D), and Weekly (W). Each timeframe is scored independently, and lower timeframes naturally lead higher timeframes in the recovery sequence. A bullish crossover on the 4H RSI typically fires days before the equivalent signal appears on the Daily chart, and the Weekly RSI is the last to confirm. This natural cascading behavior is what allows the engine to detect recovery in its earliest stages. The 4H data provides the earliest detection of the recovery turning point: while the daily RSI21 was still below 45 on April 6-7, the 4H RSI had already crossed above 45 on April 1, and would cross above 50 on April 8 morning session.

Timeframe	Role	Data Bars	Key Advantage
4H	Early detection of recovery signals	2,269 bars (2021-2026)	RSI crosses above 50 days before Daily equivalent
Daily	Primary trough detection and recovery measurement	2,094 bars (2018-2026)	Standard RSI analysis with 11-bar trough validation
Weekly	Broader trend context and structural confirmation	433 bars (2018-2026)	RSI56 > 50 confirms long-term trend intact even during decline

Formula and Scoring Rules

The scoring formula for the Apollo Analysis Engine is straightforward. The three core pools (A, B, C) are summed and capped at 100 points. Bonus pools A and B are then added on top, allowing the total score to exceed the core cap. This means a stock can achieve a high total score even if its core pool sum is only moderate, provided it receives substantial bonus points. Position sizing scales with the total score including bonus, so a score of 98 (85 base + 13 bonus) receives full allocation while a score of 75 (70 base + 5 bonus) receives a standard allocation. All pools score independently with no inter-pool gating: Pool B does not require Pool A signals to activate, and Bonus B does not require any core pool threshold.

Entry Score = min(100, Pool A + Pool B + Pool C) + Bonus A + Bonus B

Core Cap: min(100, 42 + 25 + 18) = 85. Bonus Maximum: 8 + 10 = 18. Absolute Maximum: 85 + 18 = 103. In the APOLLO validation, the engine achieved a score of approximately 98 on April 8, 2026 (85 base + 13 bonus), with the close at Rs 208.05, which was 11.5% below the 235 threshold.

Pool A - RSI Recovery | 42 pts

Pool A is the backbone of the Apollo Analysis Engine, carrying the heaviest weight at 42 points. It captures the core RSI dynamics that define a recovery: trough detection on multiple timeframes, recovery momentum measurement through discrete gain thresholds, the critical 4H-RSI21 crossover above 50, and multi-speed RSI alignment. Unlike the generic Scout Engine which uses continuous power-curve formulas for RSI reversal and rate-based momentum, the Apollo engine uses discrete binary signals: either RSI21 gained enough points from the trough within the allowed bar window, or it did not. This simplification makes every signal verifiable against a single row of CSV data.

Signal Table

ID	Signal	TF	Condition	Max	Apr 8 Status
A1	Trough Detected	D	RSI21 <= 40, 11-bar local minimum on Daily RSI21	10	YES (36.14)
A2	Trough Detected	4H	RSI21 <= 38, 5-bar local minimum on 4H RSI21	8	YES (35.37)
A3	Recovery Momentum	D	RSI21 gained >= 8 from trough in <= 10 bars	8	YES (+11.48 in 7 bars)
A4	Recovery Momentum	4H	RSI21 gained >= 10 from trough in <= 12 bars	6	YES (+17.32 in 12 bars)
A5	RSI21 Crossed Above 50	4H	4H-RSI21 > 50 (current bar)	6	YES (52.69)
A6	Multi-Speed Alignment	D	D-RSI21 > D-RSI36 (fast leading slow)	4	YES (47.62 > 46.06)
	Subtotal			42	42 / 42 at Apr 8

Trough Detection Parameters

The Apollo engine uses two parallel trough detection signals, one on the Daily timeframe and one on the 4H timeframe. The Daily trough (A1) is the primary gating signal: RSI21 must be at or below 40 and must be the lowest value in an 11-bar window (5 bars on each side). This ensures the trough represents a genuine price-level where selling pressure has temporarily abated, not a transient spike. The 4H trough (A2) uses a tighter window (5-bar local minimum) and a stricter RSI threshold (38 instead of 40) to compensate for the higher noise level on the 4H chart. Both troughs serve as the anchor points from which recovery momentum is measured: the RSI21 value at the trough becomes the baseline, and all subsequent recovery momentum calculations reference this baseline.

Parameter	Daily Trough (A1)	4H Trough (A2)
RSI Threshold	RSI21 <= 40	RSI21 <= 38
Local Minimum Window	11 bars (5 on each side)	5 bars (2 on each side)
Recovery Lookback	10 bars from trough	12 bars from trough
Points	10	8
APOLLO Trough Date	Mar 30, 2026 (RSI21 = 36.14)	Mar 30 13:15 (RSI21 = 35.37)

Recovery Momentum Measurement

The recovery momentum signals (A3, A4) are the key differentiator between the Apollo Analysis Engine and simpler threshold-based systems. Instead of checking only whether RSI21 has crossed above a fixed level (e.g., $RSI21 > 40$), these signals measure the rate of RSI recovery from the trough. A stock whose RSI21 has gained 11.48 points in 7 bars (APOLLO on Apr 8, from trough value 36.14 to 47.62) is showing strong recovery acceleration, even though the absolute RSI21 level is still below 50. This rate-based approach enables the engine to detect recovery earlier than threshold-based systems, which is the fundamental design philosophy of the Scout engine. The Daily signal (A3) requires a gain of 8 or more points within 10 bars, while the 4H signal (A4) requires a gain of 10 or more points within 12 bars. The 4H signal has a slightly higher threshold because 4H RSI is inherently more volatile.

This is a critical architectural difference from the "Our Script" implementation, which only checks whether RSI21 has crossed above 30, 40, or 45. Those are level-based checks that fire at different absolute RSI values regardless of where the stock started its recovery. The Apollo Analysis Engine instead measures how much RSI has recovered relative to its own trough, capturing the velocity of recovery rather than the position. This is why the Apollo engine fires at 98 points on April 8 (RSI21 has gained 11.48 points from trough) while the Our Script engine only reaches 60 points on the same date (RSI21 is at 47.62, which barely clears the 40 and 45 thresholds).

Multi-Speed Alignment

Signal A6 checks whether D-RSI21 has crossed above D-RSI36, indicating that the fastest RSI has recovered enough to lead the medium-speed RSI. During an active decline, the multi-speed RSI ordering is $RSI21 < RSI36 < RSI56$ (the fastest indicator is the weakest). This ordering reverses during recovery: RSI21 leads upward, crossing above RSI36 first, then RSI36 crosses above RSI56. The A6 signal captures the first of these crossover events, confirming that recovery momentum has shifted from the fastest indicator to the broader RSI structure. On April 8, D-RSI21 was 47.62 while D-RSI36 was 46.06, a difference of only 1.56 points, but it was the first bar where this ordering reversed, confirming the momentum shift.

Pool B - Price Structure | 25 pts

Pool B captures price structure signals that fire early in the recovery process. The defining design choice in the Apollo Analysis Engine is the use of 4H-level price structure signals (B1, B2) which fire days before their daily equivalents. On the Daily chart, Close > TP28 and Close > WC50 had not yet fired on April 8 (Close was 208.05 vs TP28 of 208.96, and WC50 was above the close). However, on the 4H chart, both conditions were already true: 4H-Close of 207.82 exceeded 4H-TP28 of 196.91 and 4H-WC50 of 205.63. This 4H-early-firing behavior is central to the Scout Engine philosophy and is why the Apollo engine includes 4H price signals alongside the Daily approaching signal.

Signal Table

ID	Signal	TF	Condition	Max	Apr 8 Status
B1	Close > TP28	4H	4H-Close > 4H-TP28	7	YES (207.82 > 196.91)
B2	Close > WC50	4H	4H-Close > 4H-WC50	6	YES (207.82 > 205.63)
B3	Approaching D-TP28	D	D-Close within 3% below D-TP28	5	YES (0.4% below 208.96)
B4	Higher Low Forming	D	Current Low > Previous Trough Low	4	YES (205.01 > 179.50)
B5	Price Above Trough + 10%	D	Close > Trough Low * 1.10	3	YES (208.05 > 197.45)
	Subtotal			25	25 / 25 at Apr 8

4H Price Structure Signals

Signals B1 and B2 are the earliest structural confirmation signals in the Apollo engine. The 4H Close crossing above the 4H TP28 (B1) fired on April 6 at 198.95, two full days before the Daily Close was anywhere near its TP28. The 4H Close crossing above the 4H WC50 (B2) fired on April 8 at 207.82, confirming that the shorter-term trend reversal was underway on the faster timeframe. These two signals contribute 13 of the 25 Pool B points and represent the most important architectural difference between the Apollo engine and the Our Script implementation, which lacks 4H-level signals entirely in Pool B. The absence of B1 and B2 from the Our Script is responsible for approximately 13 points of the score difference on April 8.

Approaching TP28 Proximity Signal

Signal B3 is the "approaching" proximity signal, a critical early-detection mechanism. Instead of requiring the Daily Close to actually cross above the Daily TP28 (which did not happen until April 9), B3 fires when the Close is within 3% below the TP28 line. On April 8, the Daily Close was 208.05 and the Daily TP28 was 208.96, a gap of only 0.91 points (0.4%). This is well within the 3% threshold, so B3 fired even though the actual crossover had not yet occurred. This is the second major architectural difference from the Our Script, which checks whether Close is approaching TP28 as a percentage of distance (within 5% for 3 pts, within 2% for 5 pts) but does NOT check the proximity to the TP28 line itself in the same way. The Apollo engine explicitly measures the gap between Close and TP28 as a percentage of TP28, enabling detection when price is converging toward a key structural level even before the actual breakout occurs.

Pool C - Multi-TF Confirmation | 18 pts

Pool C rewards cross-timeframe alignment without requiring all RSI values to be above 50. This is a deliberate design choice for the Scout engine: if the engine required all RSI values above 50, it would not fire until recovery is already well-advanced, defeating the early-detection purpose. Instead, Pool C uses four signals that confirm different aspects of multi-timeframe alignment. The cross-TF trough agreement signal (C1) confirms that both 4H and Daily troughs occurred within a tight time window, ruling out false signals from a single timeframe. The 4H $RSI_{36} > 45$ signal (C2) shows that the medium-speed RSI on the faster timeframe is recovering. The weekly $RSI_{56} > 50$ signal (C3) uses the last completed weekly bar to verify that the slowest RSI on the highest timeframe was still in bullish territory even during the decline. The daily $RSI_{21} > 45$ signal (C4) provides a moderate recovery threshold on the daily timeframe.

Signal Table

ID	Signal	TF	Condition	Max	Apr 8 Status
C1	Cross-TF Trough Agreement	Multi	D + 4H trough within 3 bars of each other	6	YES (both Mar 30)
C2	4H $RSI_{36} > 45$	4H	4H- $RSI_{36} > 45$ on current bar	4	YES (48.62)
C3	W- $RSI_{56} > 50$ (prev week)	W	Last completed weekly $RSI_{56} > 50$	4	YES (51.78)
C4	D- $RSI_{21} > 45$	D	D- $RSI_{21} > 45$ on current bar	4	YES (47.62)
	Subtotal			18	18 / 18 at Apr 8

Cross-TF Trough Agreement

Signal C1 is particularly powerful because it confirms that both the 4H and Daily timeframes identified a trough within a tight 3-bar window. For APOLLO, the 4H trough occurred on March 30 at 13:15 ($RSI_{21} = 35.37$) and the Daily trough occurred on March 30 ($RSI_{21} = 36.14$), both on the same date. This agreement significantly increases confidence that the trough is genuine and not a timeframe-specific anomaly. The 3-bar window accommodates the fact that 4H and Daily bars do not align perfectly: a 4H trough late on March 30 and a Daily trough on March 31 would still qualify. The weekly $RSI_{56} > 50$ signal (C3) provides additional context: even at the deepest point of the decline, the slowest weekly momentum indicator had not fully broken down ($RSI_{56} = 51.78$), suggesting the long-term trend structure was still intact.

Bonus Pool | 18 pts

The bonus pool provides additive points on top of the core 85-point cap. These signals capture external factors beyond RSI recovery and price structure: volume patterns, support levels, and the broader market context. Bonus points can push the total score above 85, with a maximum possible score of 103 (85 core + 18 bonus). Position sizing scales with the total score including bonus, meaning a stock with a 90 total receives a larger allocation than one with a 75 total. The bonus pools are designed to provide supplementary conviction without being critical path for the entry signal. Even with zero bonus points, the base score of $\min(100, 42+25+18) = 85$ already exceeds the

75-point Standard Entry threshold.

Bonus A - Volume and Support | 8 pts

ID	Signal	Condition	Max	Apr 8 Status
BA 1	Selling Exhaustion	Trough day volume < 30-day average volume	3	YES (6.9M < 9.4M)
BA 2	Price Holding Above Trough + 10%	Close > Trough Low * 1.10	3	YES (208.05 > 197.45)
BA 3	4H Volume Expansion on Recovery	Any 4H bar volume > 1.5x 20-bar avg in last 3 days	2	NO (no elevated 4H volume)
	Subtotal		8	6 / 8 at Apr 8

Selling exhaustion (BA1) confirms that the trough day saw below-average volume, indicating that selling pressure had dried up rather than intensified. Price holding above trough plus 10% (BA2) confirms the recovery has gained enough ground to establish a meaningful margin above the trough low. The 4H volume expansion signal (BA3) did not fire for APOLLO on April 8 because no 4H bar in the preceding 3 days showed volume exceeding 1.5 times the 20-bar average. This is a useful negative signal: it indicates that institutional buying interest has not yet entered the recovery, which is consistent with the Scout Engine catching the recovery at its earliest stage before volume confirms broader market participation.

Bonus B - Uptrend Correction Context | 10 pts

ID	Signal	Condition	Max	Apr 8 Status
BB1	52-Week High > Current * 1.5	52-week high > current close * 1.5	3	YES (466.50 > 312.08)
BB2	Multi-Touch of Support Zone	2nd+ touch of 220-235 support range	4	YES (3rd touch: Dec, Jan, Mar)
BB3	Weekly RSI21 > RSI56 Reversal Setup	W-RSI21 dropped below W-RSI56 but now rising	3	NO (44.53 < 51.78, still below)
	Subtotal		10	7 / 10 at Apr 8

Bonus B captures the broader market context that makes a recovery more probable. The 52-week high signal (BB1) confirms that the stock had significant upside from its current level, with the 52-week high of 466.50 being 2.24 times the April 8 close of 208.05. The multi-touch support zone signal (BB2) confirms that the 220-235 range had been tested multiple times (December 2025, January 2026, and March 2026), establishing it as a recognized support level. The weekly RSI reversal setup (BB3) did not fire because W-RSI21 (44.53) had not yet crossed back above W-RSI56 (51.78), indicating that the weekly-level recovery was still in its early stages on April 8. This is expected for the Scout Engine, which fires before weekly confirmation is complete.

Entry Decision Thresholds

The entry decision framework uses total score (core + bonus) to determine both the action and the position size. The thresholds are calibrated for the Scout Engine early-detection profile, where a score of 75 represents strong

multi-timeframe recovery evidence even if price has not yet broken above key moving averages. The Pilot Buy zone (50-69) is particularly important because it represents the earliest point at which a position can be initiated, typically when RSI recovery is underway on 1-2 timeframes and price is approaching but has not yet reached the TP28 line. The position is intentionally small (25-30%) to manage risk while the remaining signals develop.

Score Range	Action	Position Size	Rationale
0 - 49	DO NOT ENTER	0%	Insufficient recovery evidence
50 - 69	PILOT BUY	25 - 30%	Early recovery detected, limited exposure while monitoring
70 - 79	STANDARD ENTRY	60 - 70%	Solid multi-TF recovery with structural proximity
80 - 89	FULL ENTRY	100%	Strong recovery across multiple domains
90+	FULL ENTRY (Strong)	100%	Maximum signal agreement with bonus support

Score Simulation at Key Dates

The table below simulates the Apollo Analysis Engine score at several key dates during the APOLLO recovery from the March 30 trough. This demonstrates how the signal evolves over time and confirms that the score crosses the 75-point threshold while price is still well below 235. The critical transition occurs on April 8, 2026, when the score jumps from approximately 62 to 85 (base) plus approximately 13 bonus points, resulting in a total score near 98. This jump is driven by the simultaneous firing of five signals: A3 (daily recovery momentum gained ≥ 8 points), A5 (4H-RSI21 > 50), B2 (4H-Close $> 4H-WC50$), B3 (daily approaching TP28 within 3%), and C4 (daily RSI21 > 45). At this point, the price is 208.05, which is 11.5% below the 235 threshold.

Date	Close	Pool A	Pool B	Pool C	Base	Bonus	Total	Class
Mar 24	199.73	24	7	10	41	~5	~46	No Entry
Mar 30	182.16	18	7	10	35	~5	~40	No Entry
Apr 01	195.77	32	10	10	52	~6	~58	Pilot Buy
Apr 06	199.86	28	14	14	56	~6	~62	Pilot Buy
Apr 07	198.02	28	14	14	56	~6	~62	Pilot Buy
Apr 08	208.05	42	25	18	85	13	~98	Full Strong
Apr 09	232.52	42	32	18	92	15	~100+	Full Strong

The discrimination check confirms that the matrix does not produce false signals on earlier bounces within the decline. At Trough T1 (December 17, 2025, Close=223.55, RSI21=35.22), the score was approximately 26 points because only the trough detection signals (A1, A2) and basic structure signals (B4, B5) were active. No recovery momentum signals had fired yet because T1 was the trough itself. At Trough T2 (January 23, 2026, Close=222.40, RSI21=38.03), the score was similar at approximately 28 points. The December 19 recovery bounce (Close=237.95, RSI21=43.56) reached approximately 39 points, still well short of the 50-point Pilot Buy threshold. This confirms that the Apollo Analysis Engine has strong discrimination power against false signals during sustained decline phases.

Consolidated Weight Summary

The table below provides a complete view of the Apollo Analysis Engine scoring structure, showing every signal, its pool allocation, maximum possible points, and the April 8 verification status. This serves as the definitive reference for implementation, backtesting, and comparison against other engine configurations. The 19 signals across 5 pools produce a maximum possible score of 103 points, with a core cap of 85 points from the three main pools.

Pool	Signal	Max Pts	Apr 8 Status
A	Trough Detected (D)	10	YES
A	Trough Detected (4H)	8	YES
A	Recovery Momentum (D)	8	YES
A	Recovery Momentum (4H)	6	YES
